String matching Data Structures and Algorithms for Cor (ISCL-BA-07) Çağrı Çöltekin ccoltekin@sfs.uni-tuebingen.de

Winter Semester 2022/23

Types of problems

- The efficiency and usability of algorithms depend on some properties of the
 - Typical applications are based on finding multiple occurrences of a single pattern in a text, where the pattern is much shorter than the text
 The efficiency of the algorithms may depend on the
- - relative size of the pattern
 expected number of repetitions
 size of the alphabet
 whether the pattern is used once or many tir
 - · Another related problem is searching for multiple patterns at once
 - . In some cases, fuzzy / approximate search may be required

 - In some applications, preprocessing (indexing) the text to be searched may be beneficial

Brute-force string search

LAATAGACGGCTAGCAA

- - Start from the beginning, of i = 0 and j = 0
- if j == m, announce success with s = t
 if t[i] == p[j]: shift p (increase i, set j = 0]
 otherwise: compare the next character (in se i and i reneat)

Finding patterns in a string

. Finding a pattern in a larger text is a common problem in ma . Typical example is searching in a text editor or word pro-There are many more:

DNA sequencing / bioinformatics
 Plagiarism detection

Search engines / information retrieval
 Spell checking

Problem definition

feat: A A T A G A C G G C T A G C A A

* We want to find all occurrences of pattern p (length m) in text t (length n) \star The characters in both t and p are from an alphabet Σ , in the example $\Sigma = \{A, C, G, T\}$

. The size of the alphabet (q) is often an important factor p occurs in t with shift s if p[0: m] -- t[s:s+m], we have a match at s = 3 in the example

* A string x is a prefix of string y, if y = xw for a possibly empty string w * A string x is a suffix of string y, if y = wx for a possibly empty string w

Otherwise, align the last occurrence of t[i] in p with t[i] Boyer-Moore algorithm Boyer-Moore algorithm A A A T A A G C G A A T A A G A C AAATAAGCGAATAAGAC AGAC A G A C . The main idea is to start comparing from the end of p $\ast\,$ The main idea is to start comparing from the end of p If t[i] does not occur in p, shift m steps If t[i] does not occur in p, shift m steps Otherwise, align the last occurrence of t[i] in p with t[i] \star Otherwise, align the last occurrence of t[i] in p with t[i]Boyer-Moore algorithm Boyer-Moore algorithm last - {} for j in range(m): last[P[j]] - j i,j = m-1, m-1 shile i < m: if T[i] -- P[j]: if j -- 0: AAATAAGCGAATAAGAC On average, the algorithm performs better than brute-force A G A C In worst case the complexity of the algorithm is O(nm), example: t = aaa ... a, p = baa ... a. The main idea is to start comparing from the end of p Faster versions exist (O(n+m+q)) \bullet If t[i] does not occur in p, shift m steps k = last.get(T[i], -1) i += m + min(j, k+1) j = m - 1 Otherwise, align the last occurrence of t[i] in p with t[i]

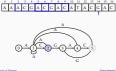

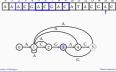

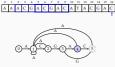

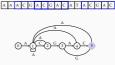

PSA pattern matching

FSA pattern matching

PSA pattern matching

PSA for string matching

* An FSA results in $O(\ensuremath{n})$ time matching, however, we need to first build the

- . At any state of the ar
- failing matches
- Given substring s recognized by a state and a non-matching input sym we want to find the longest prefix of s such that it is also a suffix of sa
- * A naïve attempt results in $O(qm^3)$ time for building the automaton (where q is the size of the alphabet m is the length of the pattern)
- + If stored in a matrix, the space requirement is O(qm)

- Better (faster) algorithms exist for construction these automaton (we will cover some later in this course)

Knuth-Morris-Pratt (KMP) algorithm

- * The KMP algorithm is probably the most popular algorithm for string

 - The idea is similar to the PSA approach: on failure, continue comparing from the longest matched prefix so fa However, we rely on a simpler data st
 - where to back up) . Construction of the table is also faste

KMP algorithm

- . In case of a match, increment both i and j
- + On failure, or at the end of the pattern, decide which new p[j] compare with t[i] based on a function f
- f[j 1] tells which j value to resume the comparisons from
